## Lowest Common Ancestor

A tree is an undirected graph in which any two vertices are connected by exactly one simple path. In other words, any connected graph without cycles is a tree. - Wikipedia

The lowest common ancestor (LCA) is a concept in graph theory and computer science. Let T be a rooted tree with N nodes. The lowest common ancestor is defined between two nodes v and w as the lowest node in $T$ that has both $v$ and $w$ as descendants (where we allow a node to be a descendant of itself). - Wikipedia

Your task in this problem is to find the LCA of any two given nodes $v$ and $w$ in a given tree $T$.

For example the LCA of nodes 9 and 12 in this tree is the node number 3.

## Input

The first line of input will be the number of test cases. Each test case will start with a number N the number of nodes in the tree, $1<=\mathrm{N}<=1,000$. Nodes are numbered from 1 to N . The next N lines each one will start with a number $M$ the number of child nodes of the Nth node, $0<=\mathrm{M}<=$ 999 followed by M numbers the child nodes of the Nth node. The next line will be a number Q the number of queries you have to answer for the given tree $T, 1<=Q<=1000$. The next $Q$ lines each one will have two number $v$ and $w$ in which you have to find the LCA of $v$ and $w$ in $T, 1<=v$, $\mathrm{w}<=1,000$.

Input will guarantee that there is only one root and no cycles.

## Output

For each test case print $Q+1$ lines, The first line will have "Case $C$ :" without quotes where $C$ is the case number starting with 1 . The next $Q$ lines should be the LCA of the given $v$ and $w$ respectively.

## Example

Input:
1
7
3234
0
3567
0
0
0
0
2
57
27

## Output:

Case 1:
3
1
